

# Does the COVID Jab Kill More People Than It Saves?

*Have you noticed the jabbed and boosted are testing positive for COVID more often than the unvaccinated? Is it pure coincidence or could there be a connection between the number of shots you receive and your risk for coming down with COVID? Here's what the latest data reveal.*

Story at-a-glance

- According to U.S. Centers for Disease Control and Prevention data, more than 1 million excess deaths – that is, deaths in excess of the historical average – have been recorded since the COVID-19 pandemic began two years ago, and this cannot be explained by COVID-19. Deaths from heart disease, high blood pressure, dementia and many other illnesses rose during that time
- Across the world, death rates have also risen in tandem with COVID shot administration, with the most-jabbed areas surpassing the least-jabbed in terms of excess mortality and COVID-related deaths
- According to Walgreens data, during the week of April 19 through 25, 2022, 13% of unvaccinated persons tested positive for COVID. Of those who received two doses five months or more ago, 23.1% tested positive, and of those who received a third dose five months or more ago, the positive rate was 26.3%. So, after the first booster shot (the third dose), people are at greatest risk of testing positive for COVID
- U.K. government data show the all-cause mortality rate is between 100% and 300% greater among people who got their first COVID shot 21 days or more ago. The risk for all-cause death is also significantly elevated among those who got their second dose at least six months ago, and mildly elevated among those who got their third dose less than 21 days ago. As of January 2022, all who got one or more doses at least 21 days ago were dying at significantly elevated rates
- Other data also show that COVID mortality rates are far higher in areas with high vaccination rates, and risk-benefit analyses reveal the jabs do more harm than good in most age groups

According to U.S. Centers for Disease Control and Prevention data,[1] more than 1 million excess deaths – that is, deaths in excess of the historical average – have been recorded since the COVID-19 pandemic began two years ago, and this cannot be explained by COVID-19.

Deaths from heart disease, high blood pressure, dementia and many other illnesses rose during that time.[2] “We’ve never seen anything like it,” Robert Anderson, CDC’s head of mortality statistics, told The Washington Post in mid-February 2022.[3]

According to University of Warwick researchers, “the scale of excess non-COVID deaths is large enough for it to be seen as its own pandemic.”[4] A number of explanations have been offered, including the fact that lockdowns and other COVID restrictions discouraged or prevented people from seeking care. But another, less discussed factor may also be at play.

Across the world, death rates have risen in tandem with COVID shot administration, with the most-jabbed areas surpassing the least-jabbed in terms of excess mortality and COVID-related deaths. This flies in the face of official claims that the shots prevent severe COVID infection and lower your risk of death, be it from COVID or all causes.[5]
